June 2nd — June 30th

The main goal of this period is to implement the core framework and the global signal architecture.

- Rebuild the screen management system so that each screen acts as an isolated task, replacing the manual continuation-passing logic.
- Creating a game loop system in `atmos` that sets us up for screen management and the basic state flow of the game.
- Refactor the gold and passive systems in `objects.lua` to use reactive signals instead of direct global writes.
- The purpose of the above is to have a working project which I can incrementally add to, with the `atmos` code I write for each feature/system. This is the foundation of the implementation stage.
